On-Chip Inter-Subsystem Communication

Related Application

This application claims priority to U.S. Provisional Application Number 60/272,439, entitled "MULTI-SERVICE PROCESSOR INCLUDING A MULTI-SERVICE BUS", filed 2/28/2001, the specification of which is hereby fully incorporated by reference.

BACKGROUND OF THE INVENTION

10 1. Field of the Invention

The present invention relates to the field of integrated circuit. More specifically, the present invention relates to inter-subsystem communication between subsystems on an integrated circuit device.

15 2. <u>Background Information</u>

Advances in integrated circuit technology have led to the birth and proliferation of a wide variety of integrated circuits, including but not limited to application specific integrated circuits, micro-controllers, digital signal processors, general purpose microprocessors, and network processors. Recent advances have also led to the birth of what's known as "system on a chip" or SOC. Typically, a SOC includes multiple "tightly coupled" subsystems performing very different

; , · .

5

functions. These subsystems often have a need to communicate and cooperate with each other on a regular basis.

U.S. Patent 6,122,690 discloses an on-chip bus architecture that is both processor independent and scalable. The '690 patent discloses a bus that uses "standardized" bus interfaces to couple functional blocks to the on-chip bus. The "standardized" bus interfaces include embodiments for bus master functional blocks, slave functional blocks, or either. The '690 bus suffers from at least one disadvantage in that it does not offer rich functionalities for prioritizing interactions or transactions between the subsystems, which are needed for a SOC with subsystems performing a wide range of very different functions.

Accordingly, a more flexible approach to facilitate inter-subsystem communication between subsystems on a chip is desired.

BRIEF DESCRIPTION OF DRAWINGS

15

20

The present invention will be described by way of exemplary embodiments, but not limitations, illustrated in the accompanying drawings in which like references denote similar elements, and in which:

Figure 1 illustrates an overview of a system on-chip including an on-chip bus and a number of subsystems coupled to the on-chip bus, in accordance with one embodiment:

Figures 3a-3b illustrate a request and a reply transaction between two subsystems, in accordance with one embodiment;

Figure 4 illustrates data transfer unit of Fig. 1 in further detail, in accordance with one embodiment;

Figures 5a-5b illustrate the operational states and the transition rules for the state machines of Fig. 4, in accordance with one embodiment; and

Figures 6a-6c are timing diagrams for practicing the present invention, in accordance with one implementation.

DETAILED DESCRIPTION OF THE INVENTION

The present invention includes interface units and operational methods for flexibly facilitating inter-subsystem communication between subsystems of a SOC. In the following description, various features and arrangements will be described, to provide a thorough understanding of the present invention. However, the present invention may be practiced without some of the specific details or with alternate features/arrangement. In other instances, well-known features are omitted or simplified in order not to obscure the present invention.

The description to follow repeatedly uses the phrase "in one embodiment", which ordinarily does not refer to the same embodiment, although it may. The terms

15

20

5

"comprising", "having", "including" and the like, as used in the present application, including in the claims, are synonymous.

Overview

Referring now to **Figure 1**, wherein a block diagram illustrating an overview of a SOC **100** with subsystems **102a-102d** incorporated with the teachings of the present invention for inter-subsystem communication, in accordance with one embodiment, is shown. As illustrated, for the embodiment, SOC **100** includes on-chip bus **104** and subsystems **102a-102d** coupled to each other through bus **104**. Moreover, each of subsystems **102a-102d** includes data transfer unit or interface (DTU) **108a-108d** incorporated with teachings of the present invention, correspondingly coupling the subsystems **102a-102d** to bus **104**. SOC **100** also includes arbiter **106**, which is also coupled to bus **104**.

In one embodiment, bus 104 includes a number of sets of request lines (one set per subsystem), a number of sets of grant lines (one set per subsystem), and a number of shared control and data/address lines. Included among the shared control lines is a first control line for a subsystem granted access to the bus (grantee subsystem, also referred to as the master subsystem) to assert a control signal to denote the beginning of a transaction cycle, and to de-assert the control signal to denote the end of the transaction cycle; and a second control line for a subsystem addressed by the grantee/master subsystem (also referred to as the slave subsystem) to assert a control signal to inform the grantee/master subsystem that

15

20

5

the addressee/slave subsystem is busy (also referred to as "re-trying" the master system).

As a result of the facilities advantageously provided by DTU 108a-108d, and the teachings incorporated in subsystem 102a-102d, subsystems 102a-102d are able to flexibly communicate and cooperate with each other, allowing subsystems 102a-102d to handle a wide range of different functions having different needs. More specifically, as will be described in more detail below, in one embodiment, subsystems 102a-102d communicate with each other via transactions conducted across bus 104. Subsystems 102a-102d, by virtue of the facilities advantageously provided by DTU 108a-108d, are able to locally prioritize the order in which its transactions are to be serviced by the corresponding DTU 108a-108d to arbitrate for access to bus 104. Further, in one embodiment, by virtue of the architecture of the transactions, subsystems 102a-102d are also able to flexibly control the priorities on which the corresponding DTU 108a-108d are to use to arbitrate for bus 104 with other contending transactions of other subsystems 102a-102d.

Arbiter 106 is employed to arbitrate access to bus 104. That is, arbiter 106 is employed to determine which of the contending transactions on whose behalf the DTU 108a-108d are requesting for access (through e.g. the request lines of the earlier described embodiment), are to be granted access to bus 104 (through e.g. the grant lines of the earlier described embodiment).

SOC **100** is intended to represent a broad range of SOC, including multiservice ASIC. In particular, in various embodiments, subsystems **102a-102d** may be

15

20

SOC 100.

5

one or more of a memory controller, a security engine, a voice processor, a collection of peripheral device controllers, a framer processor, and a network media access controller. Moreover, by virtue of the advantageous employment of DTU 108a-108d to interface subsystems 102a-102d to on-chip bus 104, with DTU 108a-108d and on-chip bus operating on the same clock speed, the core logic of subsystems 102a-102d may operate in different clock speeds, including clock speeds that are different from the clock speed of non-chip bus 104 and DTU 108a-

108d. In one embodiment, one or more subsystems 102a-102d may be a multi-

function subsystems, in particular, with the functions identified by identifiers. Except

for the teachings of the present invention incorporated into subsystems 102a-102d,

the exact constitution and the exact manner their core logic operate in providing the

functions/services the subsystems are immaterial to the present invention. While for

ease of understanding, SOC 100 is illustrated as having only four subsystems 102a-

102d, in practice, SOC **100** may have more or less subsystems. In particular, by

102a-102d to on-chip bus 104, zero or more selected ones of subsystems 102a-

virtue of the advantageous employment of DTU 108a-108d to interface subsystems

102d may be removed, while other subsystems 102a-102d may be flexibly added to

Similarly, arbiter **106** may be any one of a number of bus arbiters known in the art. The facilities of DTU **108a-108d** and the teachings incorporated into the core logic of subsystems **102a-102d** to practice the present invention will be described in turn below.

15

20

5

<u>Method</u>

Referring now to **Fig. 2**, wherein a flow chart illustrating a method of the present invention, in accordance with one embodiment, is shown. As illustrated, in accordance with the present invention, subsystems **102a-102d** initiate transactions with one another, using the facilities of their corresponding DTU **108a-108d** to locally prioritize the order the transactions of the corresponding subsystems are to be serviced, for arbitration for access to bus **104**, block **202**.

Further, for the embodiment, for each transaction, each subsystem 102a102d also includes as part of the transaction the bus arbitration priority the
corresponding DTU 108a-108d is to use to arbitrate for access to bus 104, when
servicing the transaction in the prioritized manner.

In response, DTU **108a-108d** service the transactions of the respective subsystems **102a-102d** accordingly, and arbitrating for access to bus **104**, using the bus arbitration priorities included among the transactions. Arbiter **106** in turn grants accesses to bus **104** based on the bus arbitration priorities of the contending transactions, block **204**.

In one embodiment, arbiter **106** grants access strictly by the transaction priorities, e.g. in a three priority implementation, all high priority transactions will be granted access first, before the medium priority transactions are granted access, and finally the low priority transactions are granted access. In another embodiment, arbiter **106** further employs certain non-starvation techniques, to ensure the medium

15

20

5

and/or low priority transactions will also be granted access to bus **104**. The non-starvation techniques may be any one of a number of such techniques known in the art.

Still referring to **Figure 2**, once granted access to bus **104**, the grantee DTU **108*** places the grantee transaction on bus **104** (through e.g. the shared data/address lines of the earlier described embodiment). In one embodiment, the transaction includes address of the targeted subsystem **102***. In response, once placed onto bus **104**, the addressee subsystem **102*** claims the transaction, and acknowledges the transaction, or if the subsystem **102*** is busy, instructs the requesting subsystem **102*** to retry later, block **206**. If acknowledgement is given and a reply is due (as in the case of a read request), the reply is later initiated as a reply transaction. In other words, for the embodiment, "read" transactions are accomplished in a "split" manner.

In the present application, for ease of designation, the trailing "*" of a reference number denotes one of the instances of reference. For example, 108* means either 108a, 108b, 108c or 108d.

Exemplary Transaction Formats

Figures 3a-3b illustrate two exemplary transaction formats, a request format and a reply format, suitable for use to practice the present invention, in accordance with one embodiment. As illustrated in Fig. 3a, exemplary request transaction 302 includes three parts, first header 301a, second header 301b, and optional data

15

20

5

portion 312. First header 301a includes in particular, a command or request code 304, which for the embodiment, includes the bus arbitration priority, and address 306 of the target subsystem 102*. The various subsystems 102a-102d of SOC 100 are assumed to be memory mapped. Arbitration is initiated by a DTU 108* requesting arbiter 106 for access (through e.g. the earlier described subsystem based request lines), including with the request the included bus arbitration priority in the command portion 304 of first header 301a. Second header 301b includes an identifier identifying a function of the originating subsystem 102*, allowing subsystem 102* to be a multi-function subsystem and be able to associate transactions with the various functions. Second header 301b also includes size 310. For write transactions, size 310 denotes the size of the write data to follow (the "optional" data portion), in number of bytes. For read transactions, size 310 denotes the size of the data being accessed (i.e. read), also in number of bytes.

As illustrated in Fig. 3b, exemplary reply transaction 322 also includes three parts, first header 321a, second header 321b and data 332. First header 321a includes in particular, a command or request code 324, which includes the bus arbitration priority, identifier 328 which identifies the subsystem and its function, and low order byte of targeted address 326a of the replying subsystem 102*. As alluded earlier, data 332 includes the data being accessed/read by the original read request. Again, arbitration is initiated by a DTU 108* requesting arbiter 106 for access (through e.g. the earlier described subsystem based request lines), including with the request the included bus arbitration priority in the command portion 324 of first

header **321a**. Second header **321b** includes the remaining high order bytes targeted address **326a** of the replying subsystem **102***. Accordingly, employment of these transaction formats enables a subsystem **102*** to communicate with another subsystem **102*** at any byte position, reducing the number of operations for unaligned data transfers.

In one embodiment, different commands are supported for "conventional" data versus control, and voice data. More specifically, for the embodiment, the commands supported are:

| Command Code | Command | Description |
|--------------|----------|-----------------------|
| | | |
| 000 | Reserved | Reserved |
| 001 | DRead | Data Read Request |
| 010 | CRead | Control Read Request |
| 011 | VRead | Voice Read Request |
| 100 | DWrite | Data Write Request |
| 101 | CWrite | Control Write Request |
| 110 | VWrite | Voice Write Request |
| 111 | Reply | Read Reply |

15

20

5

Data Transfer Units

Figure 4 illustrates DTU 108* in further details, in accordance with one embodiment. As illustrated, DTU 108* includes a number of pairs of outbound and inbound transaction queues 402* and 404*, one pair each for each priority level. For example, in one embodiment where DTU 108* supports three levels of priority, high, medium and low, DTU 108* includes three pairs of outbound and inbound transaction queues 402a and 404a, 402b and 404b, and 402c and 404c, one each for the high, medium and low priorities. In another embodiment, DTU 108* supports two levels of priority, high and low, DTU 108* includes two pairs of outbound and inbound transaction queues 402a and 404a, and 402b and 404b, one each for the high and low priorities. Of course, in other embodiments, DTU 108* may support more than three levels of priority or less than two levels of priority, i.e. no prioritization.

Additionally, DTU 108* includes outbound transaction queue service state machine 406 and inbound transaction queue service state machine 408, coupled to the transaction queues 402* and 404* as shown. Outbound transaction queue service state machine 406 services, i.e. processes, the transactions placed into the outbound queues 402* in order of the assigned priorities of the queues 402* and 404*, i.e. with the transactions queued in the highest priority queue being serviced first, then the transaction queued in the next highest priority queue next, and so forth.

15

20

5

outbound queue 402* to output on the subsystem's request lines, the included bus arbitration priority of the first header of the "oldest" (in turns of time queued) transaction of the queue 402*, to arbitrate and compete for access to bus 104 with other contending transactions of other subsystems 102*. Upon being granted access to bus 104 (per the state of the subsystem's grant lines), for the embodiment, outbound transaction queue service state machine 406 provides the control signals to the queue 402* to output the remainder of the transaction, e.g. for the earlier described transaction format, the first header, the second header and optionally, the trailing data.

Similarly, inbound transaction queue service state machine 408 provides the control signals to the corresponding inbound queue 402* to claim a transaction on bus 104, if it is determined that the transaction is a new request transaction of the subsystem 102* or a reply transaction to an earlier request transaction of the subsystem 102*. Additionally, in one embodiment, if the claiming of a transaction changes the state of the queue 404* from empty to non-empty, inbound transaction queue service state machine 408 also asserts a "non-empty" signal for the core logic (not shown) of the subsystem 102*.

For each of the transactions being serviced, outbound transaction queue

service state machine 406 provides the control signals to the corresponding

In due course, the core logic, in view of the "non-empty" signal, requests for the inbound transactions queued. In response, inbound transaction queue service state machine **408** provides the control signals to the highest priority non-empty

5

21022 P(

inbound queue to cause the queue to output the "oldest" (in turns of time queued) transaction of the queue **404***. If all inbound queues **404*** become empty after the output of the transaction, inbound transaction queue service state machine **408** deasserts the "non-empty" signal for the core logic of the subsystem **102***.

Thus, under the present invention, a core logic of a subsystem 102* is not only able to influence the order its transactions are being granted access to bus 104, relatively to transactions of other subsystems 102*, through specification of the bus arbitration priorities in the transactions' headers, a core logic of a subsystem 102*, by selectively placing transactions into the various outbound queues 402* of its DTU 108*, may also utilize the facilities of DTU 108* to locally prioritize the order in which its transactions are to be serviced to arbitrate for access for bus 104.

Queue pair 402* and 404* may be implemented via any one of a number of "queue" circuitry known in the art. Similarly, state machines 406-408, to be described more fully below, may be implemented using any one of a number programmable or combinatory circuitry known in the art. In one embodiment, assignment of priorities to the queues pairs 402* and 404* are made by programming a configuration register (not shown) of DTU 108*. Likewise, such configuration register may be implemented in any one of a number of known techniques.

20

15

15

20

5

State Machines

Referring now to **Figures 5s** and **5b** wherein two state diagrams illustrating the operating states and transitional rules of state machines **406** and **408** respectively, in accordance with one embodiment, are shown. The embodiment assumes three pairs of queues **402a** and **404a**, **402b** and **404b**, and **402c** and **404c**, having three corresponding level of assign priorities, high, medium and low.

As illustrated in Fig. 5a, initially, for the embodiment, state machine 406 is in idle state 502. If state machine 406 detects that the high priority queue 402a is non-empty, it transitions to first arbitrate state 504, and arbitrate for access to bus 104 for the "oldest" (in terms of time queued) transaction queued in the high priority queue 402a. However, if while in idle state 502, state machine 406 detects that the high priority queue 420a is empty and the medium priority queue 402b is not empty, it transitions to second arbitrate state 508, and arbitrate for access to bus 104 for the "oldest" (in terms of time queued) transaction queued in the medium priority queue 402b. Similarly, if while in idle state 502, state machine 406 detects that both the high and medium priority queues 402a-402b are empty, and the low priority queue 402c is not empty, it transitions to third arbitrate state 512, and arbitrate for access to bus 104 for the "oldest" (in terms of time queued) transaction queued in the low priority queue 402c. If none of these transition conditions are detected, state machine 406 remains in idle state 502.

Upon arbitrating for access to bus **104** for the "oldest" (in terms of time queued) transaction queued in the highest priority queue **402a** after entering first

15

20

5

arbitrate state **504**, state machine **406** remains in first arbitrate state **504** until the bus access request is granted. At such time, it transitions to first placement state **506**, where it causes the granted transaction in the high priority queue **404a** to be placed onto bus **104**.

From first placement state **506**, state machine **406** returns to one of the three arbitrate states **504**, **508** and **512** or idle state **502**, depending on whether the high priority queue **402a** is empty, if yes, whether the medium priority queue **402b** is empty, and if yes, whether the low priority queue **402c** is also empty.

Similarly, upon arbitrating for access to bus **104** for the "oldest" (in terms of time queued) transaction queued in the medium priority queue **402b** after entering second arbitrate state **508**, state machine **406** remains in second arbitrate state **508** until the bus access request is granted. At such time, it transitions to second placement state **510**, where it causes the granted transaction in medium priority queue **402b** to be placed onto bus **104**.

From second placement state **510**, state machine **406** returns to one of the three arbitrate states **504**, **508** and **512** or idle state **502**, depending on whether the high priority queue **402a** is empty, if yes, whether the medium priority queue **402b** is empty, and if yes, whether the low priority queue **402c** is also empty.

Likewise, upon arbitrating for access to bus **104** for the "oldest" (in terms of time queued) transaction queued in the low priority queue **402c**, state machine **406** remains in third arbitrate state **512** until the bus access request is granted. At such

15

20

5

time, it transitions to third placement state **514**, where it causes the granted transaction in low priority queue **402b** to be placed onto bus **104**.

From third placement state **514**, state machine **406** returns to one of the three arbitrate states **504**, **508** and **512** or idle state **502**, depending on whether the high priority queue **402a** is empty, if yes, whether the medium priority queue **402b** is empty, and if yes, whether the low priority queue **402c** is also empty.

As illustrated in **Fig. 5b**, initially, for the embodiment, state machine **408** is also in idle state **602**. While at idle state **602**, if no transaction on bus **104** is addressed to the subsystem **102*** (or one of the functions of the subsystem **102***, in the case of a reply transaction), nor are there any pending request for data from the core logic of the subsystem **102***, state machine **408** remains in idle state **602**.

However, if the presence of a transaction on bus **104** addressed to the subsystem **102*** (or one of the functions of the subsystem **102***, in the case of a reply transaction) is detected, state machine **408** transitions to claim state **604**, where it provides control signals to the appropriate queue **404*** to claim the transaction, and acknowledges the transaction.

If claiming of the transaction changes the state of the queues from all empty to at least one queue not empty, state machine **408** transitions to the notify state **606**, in which it asserts the "non-empty" signal for the core logic of subsystem **102***, as earlier described.

From notify state **606**, state machine **408** transitions to either claim state **604** if there is another transaction on bus **104** addressed to the subsystem **102*** (or a

5

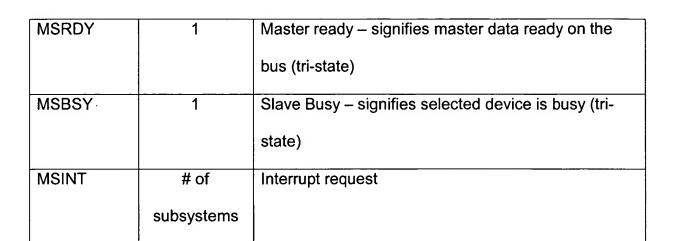

function of the subsystem 102*, in case of a reply), or output state 608, if there is a pending request for data from the core logic of the subsystem 102*. From output state 608, state machine 408 either transitions to claim state 604 another transaction on bus 104 addressed to the subsystem 102* (or a function of the subsystem 102*, in case of a reply) is detected, remains in output state 608 if there is no applicable transaction on bus 104, but request for data from the core logic is outstanding, or returns to idle state 602, if neither of those two conditions are true.

Bus Signals, Timing and Rules

In one embodiment, the bus signals supported are as follows:

| Signal Name | Signal Width | Description |
|-------------|---------------|---|
| MSCLK | 1 | Bus Clock (e.g. 25 – 100 MHz) |
| MSRST | 1 | System Bus Reset |
| MSAD[31:0] | 32 | Address/Data (tri-state, bi-directional) |
| MSCYC | 1 | Shared among subsystems to denote master bus |
| | | cycles |
| MSREQ-1:0] | pair for each | Bus request, 2 per subsystem to gain ownership of |
| | subsystem | bus |
| MSGNT | # of | Bus grant – signifies subsystem own the bus |
| | subsystems | |
| MSSEL | 1 | Slave select – signifies subsystem has been |
| | | selected (tri-state) |

10

In one embodiment, the request codes supported are as follows:

| | Req[1:0] | Request Type |
|----|----------|------------------------------------|
| 00 | | Idle – no request |
| 01 | | Low priority ("conventional" Data) |
| 10 | | Medium priority (Control) |
| 11 | | High priority (Voice and Replies) |

Figures 6a-6c are three timing diagrams illustrating the timings of the various signals of the above described embodiment, for burst write timing, write followed by read timing and read followed by write timing (different subsystems) respectively.

In one embodiment, the maximum burst transfer size is 64-bytes of data (+ 8 bytes for the transaction header). The subsystems guarantee the burst transfers to be within a page. The slave devices would accept the maximum sized transfer (64 bytes + header) before generating the above described MSSEL signal.

15

20

5

In one embodiment, each data transfer unit would permit only one Read request to be outstanding. If a Read request is pending, the subsystem would not accept requests from other masters until the reply to the outstanding Read request has been received. This advantageously prevents a deadlock condition. The subsystem may, however, continue to generate write requests.

In alternate embodiments, the present invention may be practiced with other approaches being employed to address these and other operational details.

Conclusion and Epilogue

Thus, it can be seen from the above descriptions, an improved method and apparatus for inter-subsystem communication between subsystems of a SOC has been described. The novel scheme advantageously enables the core logic of the subsystems to operate in different clock domains. Moreover, the novel scheme enables subsystems to be flexibly added to or removed from a particular implementation of the SOC. While the present invention has been described in terms of the foregoing embodiments, those skilled in the art will recognize that the invention is not limited to these embodiments. The present invention may be practiced with modification and alteration within the spirit and scope of the appended claims. Thus, the description is to be regarded as illustrative instead of restrictive on the present invention.
